

# GWAS 5

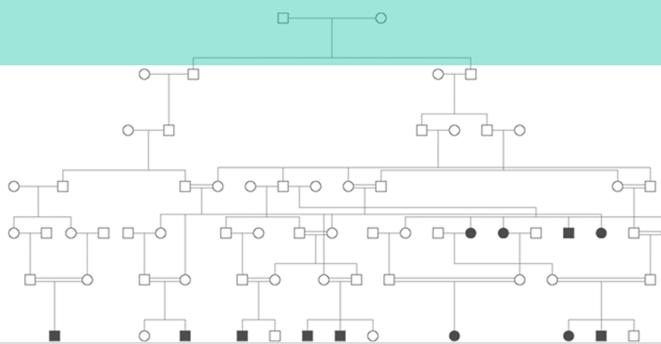

Matti Pirinen  
University of Helsinki  
11.11.2020

**A****B**

### CRYPTIC RELATEDNESS

**C**

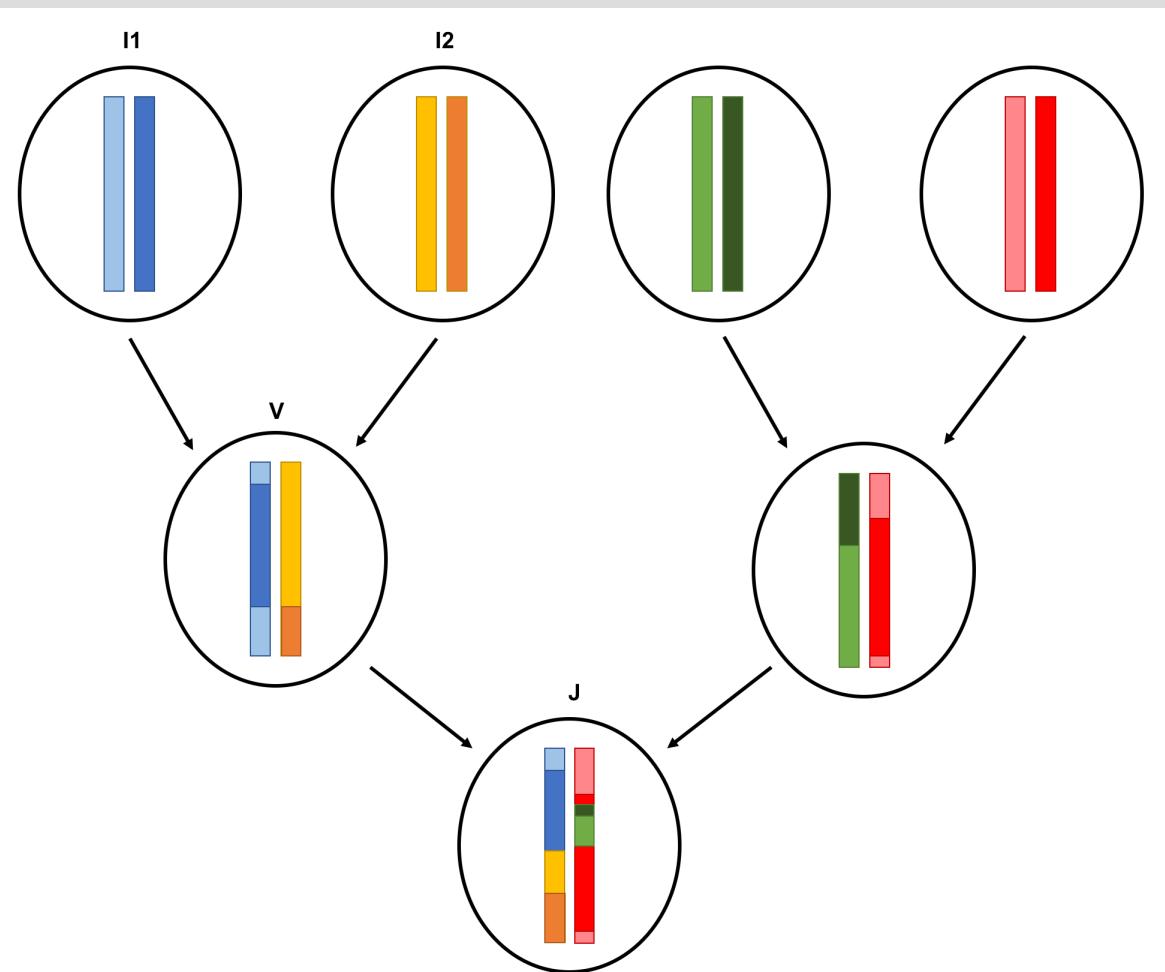

### ANCESTRY

## LEVELS OF RELATEDNESS

- (A) All of the individuals in a genetic study are related through a large pedigree or family tree. Different parts of the tree induce different types of relatedness.
- (B) **Cryptic relatedness** refers to relatively recent genetic relationships which are not otherwise reported in the data except by genetic analysis.
- (C) Relatedness due to ancestry refers to relatedness caused by ancestors originating from the same region, i.e., **population structure**.  
The boxes in (B) and (C) represent the level of the pedigree that causes that type of relatedness in each case.

# GENOMIC RECOMBINATION

Three generations are shown: 4 grandparents (top), 2 parents (middle) and an offspring (bottom).

The two genomes of each individual are shown for a particular genomic segment.

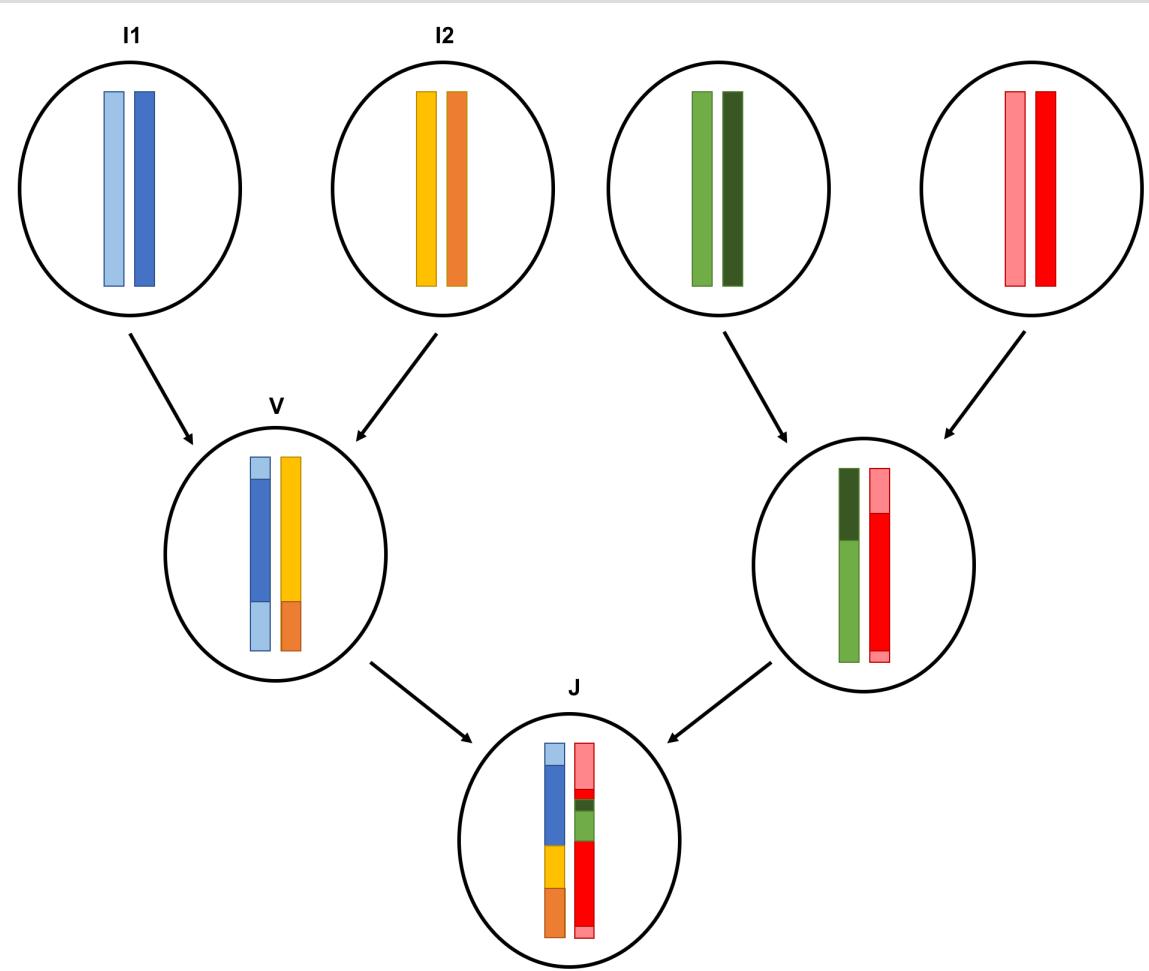

All 8 grandparental genomes are colored with separate colors.

The parents inherit recombined genomes from the grandparents, e.g., parent V inherits from grandparent I1 a combination of light blue and dark blue genomes.

Similarly, as a result of a recombination, offspring J inherits from parent V a genome that contains segments from all 4 genomes of grandparents I1 and I2.

If we took the reference level of colored genomes further back in time to more distant ancestors, we would observe shorter intact segments, and more colorful genomes, in the offspring.

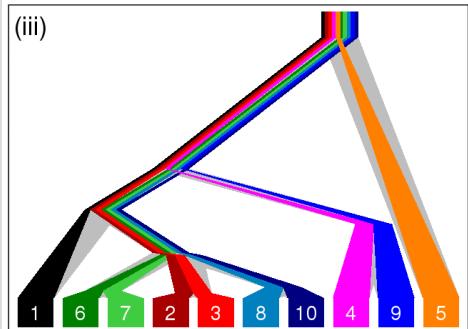

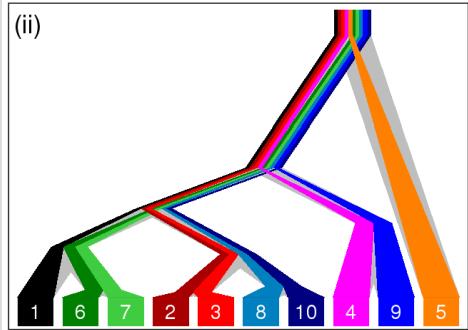

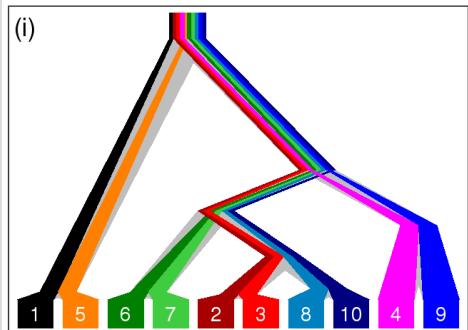

# GENOMIC RECOMBINATION

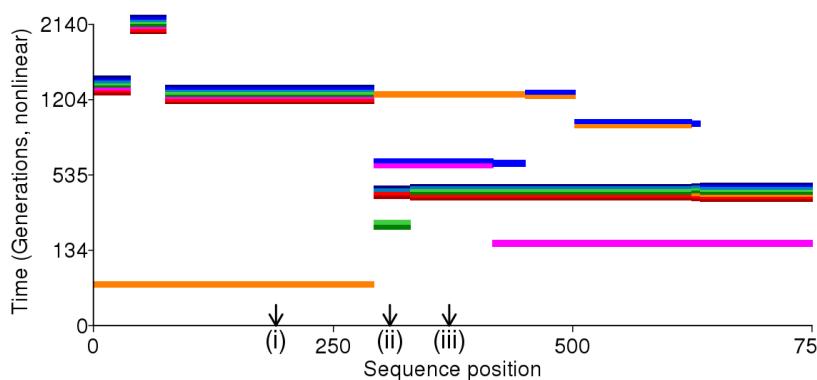

- Offspring inherits genome as continuous segments of the parent's two genomes
- Segments from recent ancestors are longer than from more distant ancestors
- This process determines correlations in genotype data
  - Genetic relatedness (today's topic)
    - sample-by-sample correlation of genotypes
    - "closer relatives share more genome"
  - GWAS results at nearby SNPs are correlated (next week)
  - SNP-by-SNP correlation of genotypes

# GENETIC RELATEDNESS IS ABOUT TIME TO MOST RECENT COMMON ANCESTOR

A) Local genealogies

B) Time to MRCA with haplotype 1

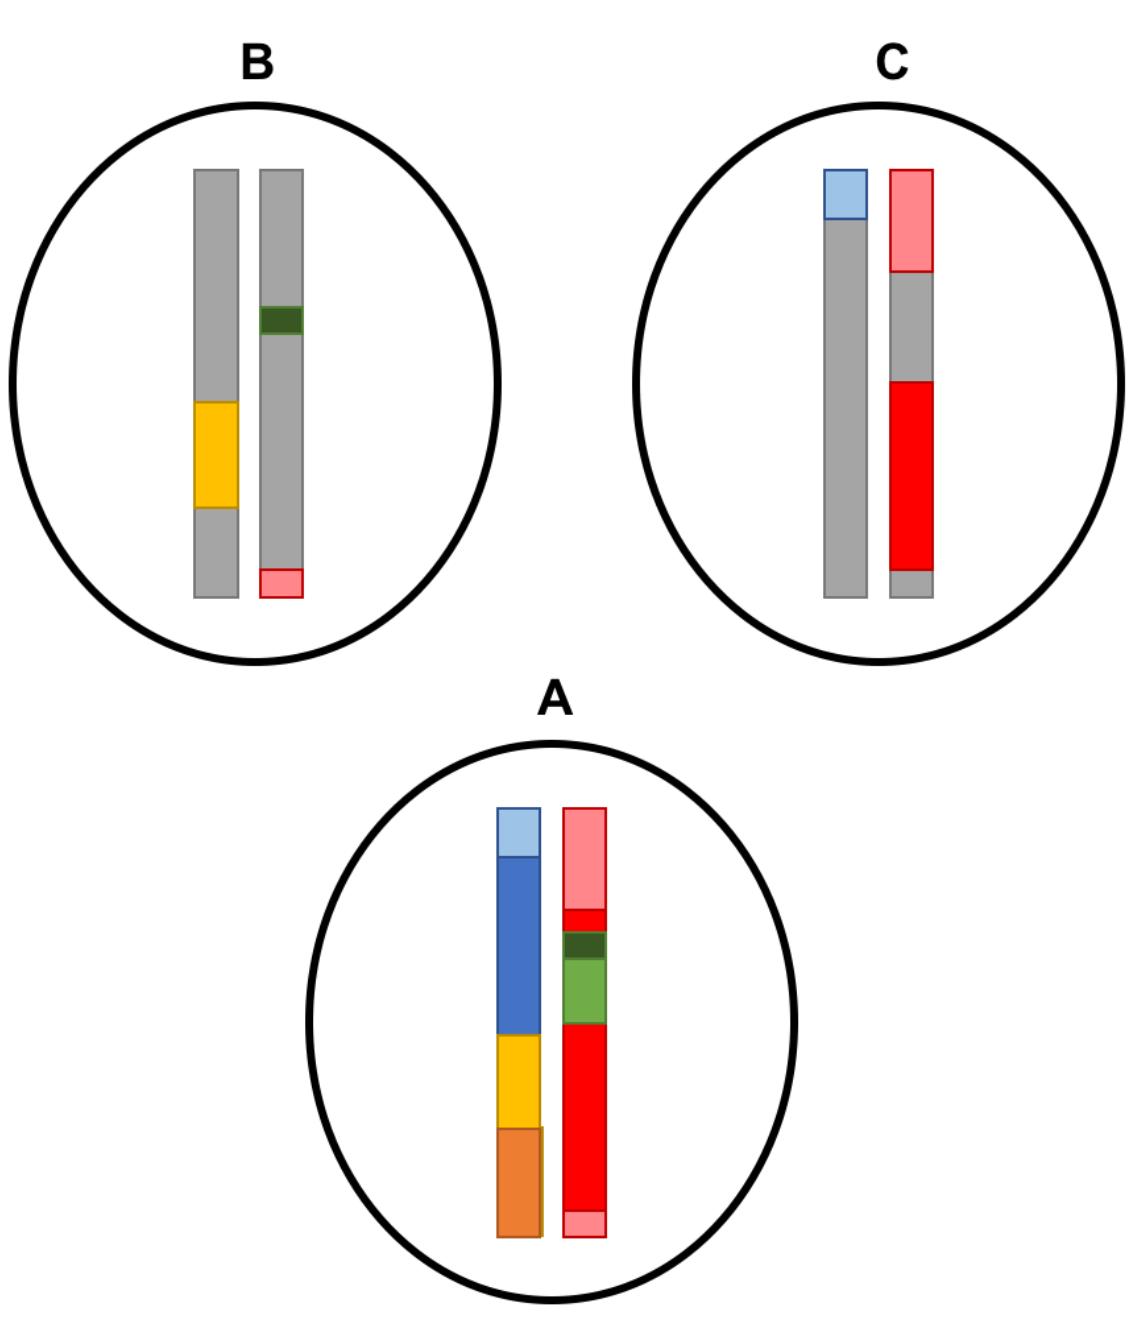

Left: the ancestral relationships between 10 genomes at 3 genomic sites.

Top: Time to most recent common ancestor with genome 1, shown for other 9 genomes.

Intuition:

Close relatives share more genetic ancestors in more recent past than distant relatives.

If we average such information across the genome we have a relatedness estimate for genomes, and if we average over two genomes of individuals we have a relatedness estimate for individuals.

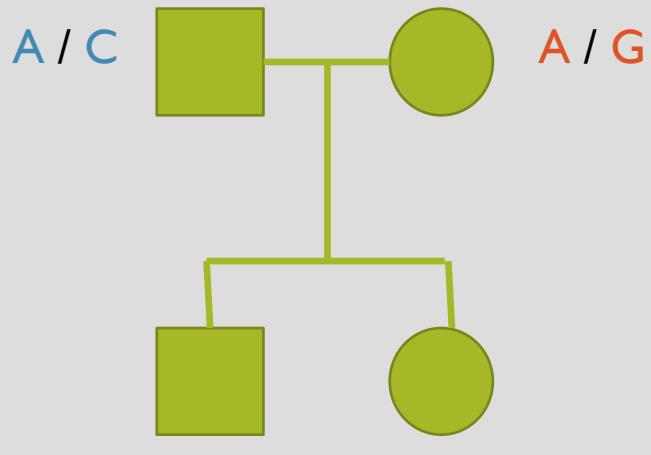

## ESTIMATING RELATEDNESS

Two genomes of individual A are colored according to their ancestral origins with respect to some time point back in time (See Slide 2). The two additional individuals B and C belong to the present day generation (as does A) and by computational methods we have estimated in which parts of the genome B and C share segments with A. The most probable matches have been colored and the rest of the genomes have been left gray.

We estimate that C is a closer relative to A than B because C and A have more shared DNA from recent ancestors than B and A.

# IBS VS IBD

	IBS	IBD	
A / G			A / A
C / A		0	A / G
A / A	2	2	A / A

- IBS (identical-by-state) means that DNA sequence is identical
- IBD (identical-by-descent) means that DNA sequence is inherited from a common ancestor (within a given timeframe)
  - For pedigrees the timeframe is founder generation
  - For population data, we don't have an exact timeframe and then IBD is measured by how much more the pair shares IBS than would be expected from a random pair from the population
- Most accurate IBD estimation methods look for sharing of longer segments not just individual loci, but here we consider sharing at independent loci
- IBD implies IBS but not vice versa: there can be IBS sharing without there being a common ancestor **within a given timeframe** (such as known pedigree structure)

# EXPECTED IBD SHARING

## Genetic Relationships Between Family Members

Percentages indicate the amount of shared DNA between YOU and each blood relative

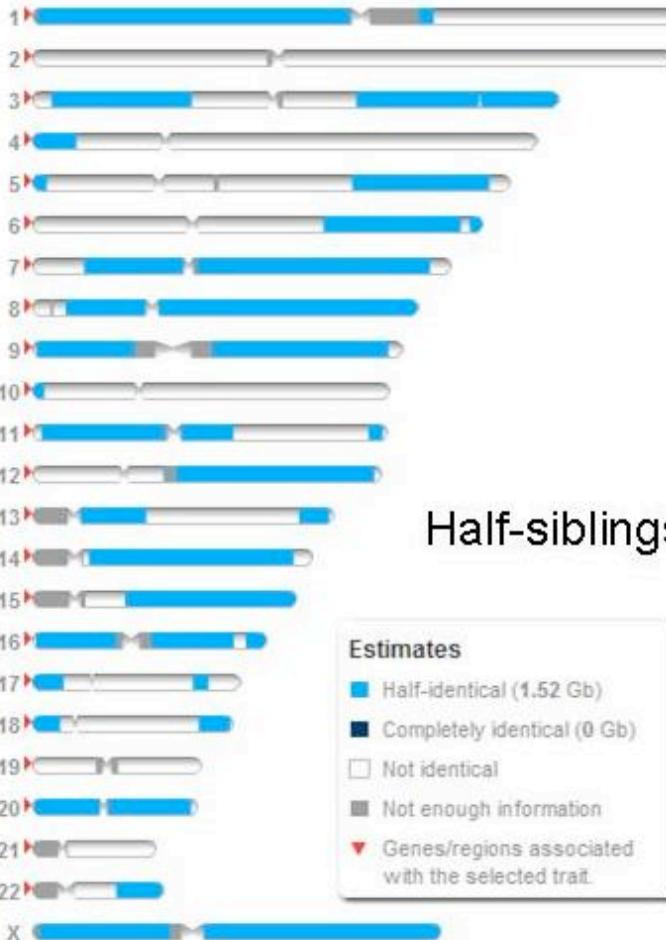

famlii

# RECENT IBD SEGEMENTS ARE INFORMATIVE

## Genome-Wide Comparison

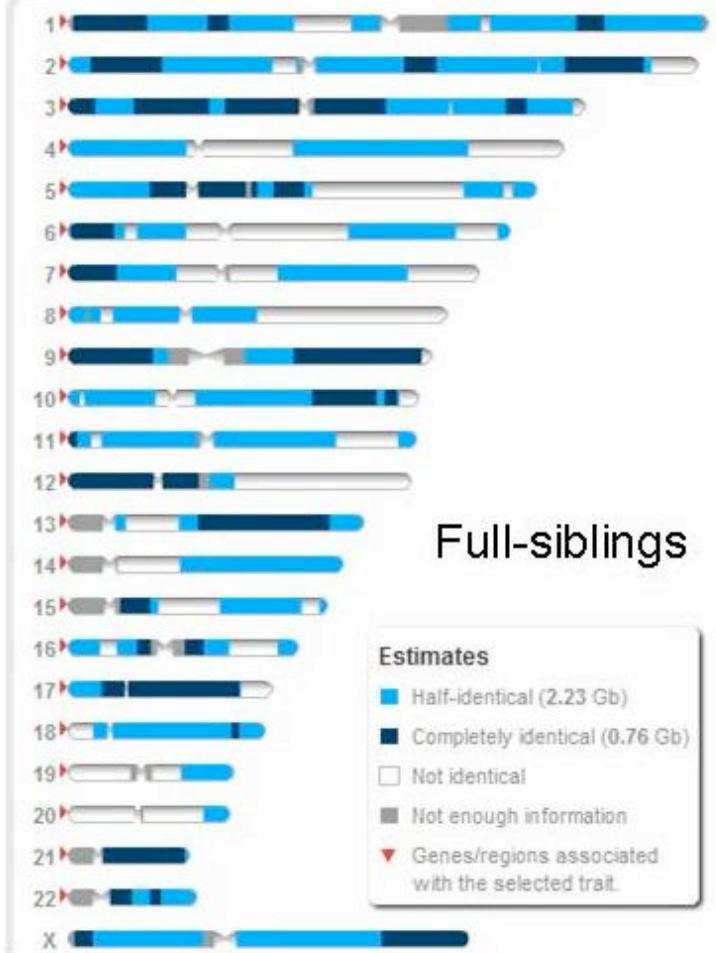

Comparison across all of the genome data

Half-siblings

## Genome-Wide Comparison

Comparison across all of the genome data

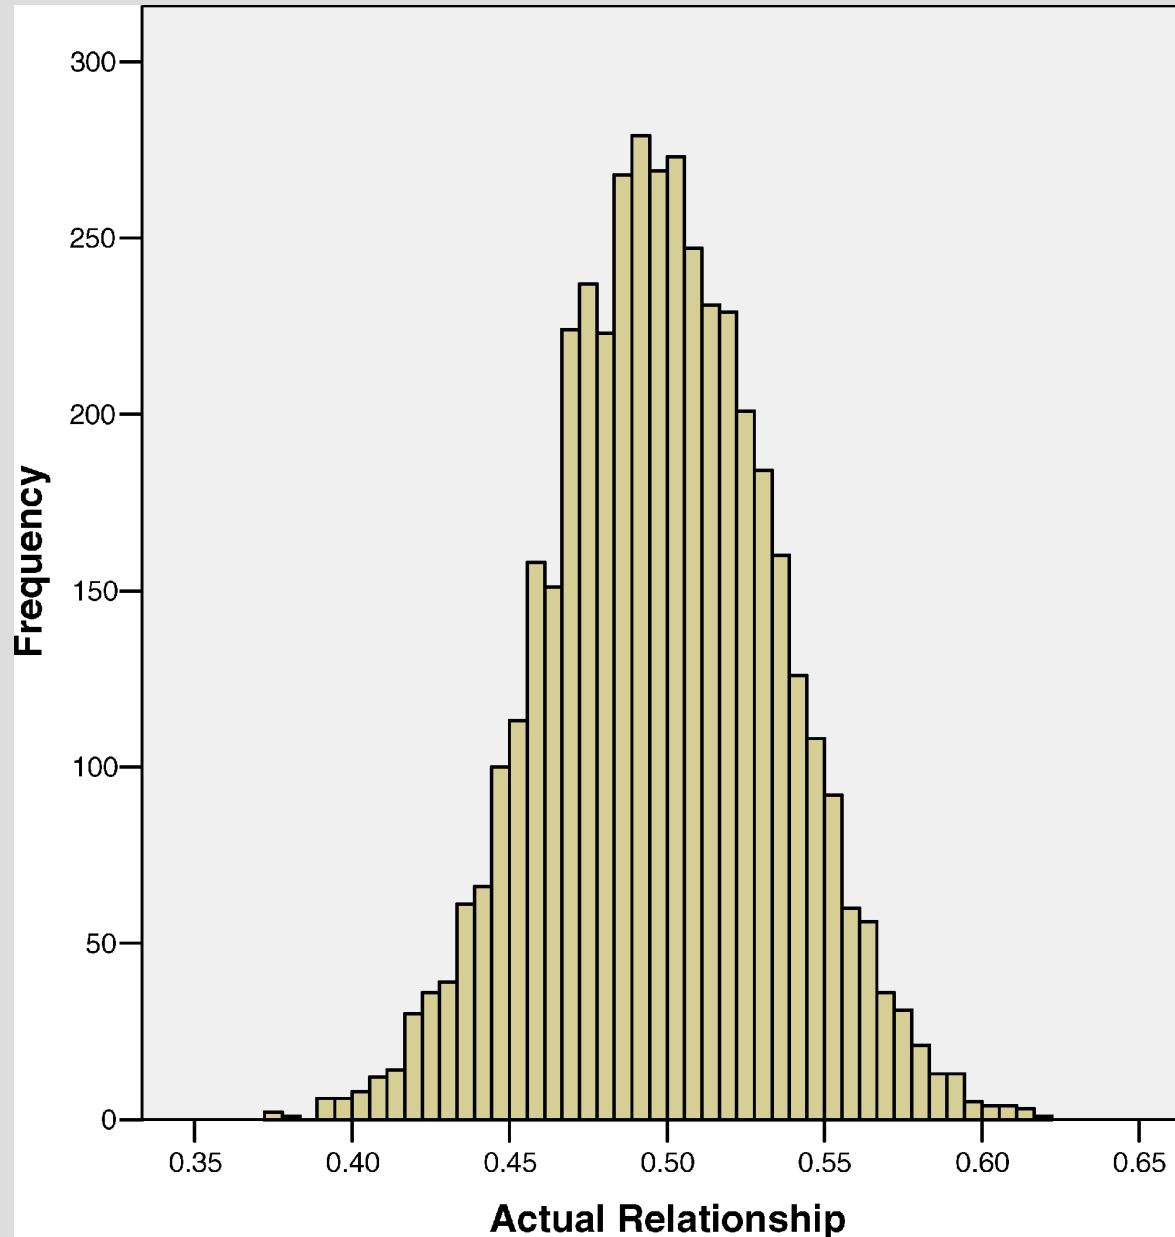

Full-siblings

Each panel describes estimated IBD Sharing between one pair of individuals.

Left pair seem like half-siblings as they Share half of the genome IBD1

Right pair seem full-sibs as they share 25% IBD2, 50% IBD1 and 25% IBD0.

Relatedness coefficient  $r_{ij}$  for half-sibs is ~25% and for full sibs is ~50%.

## FULL SIBLINGS' IBD SHARING

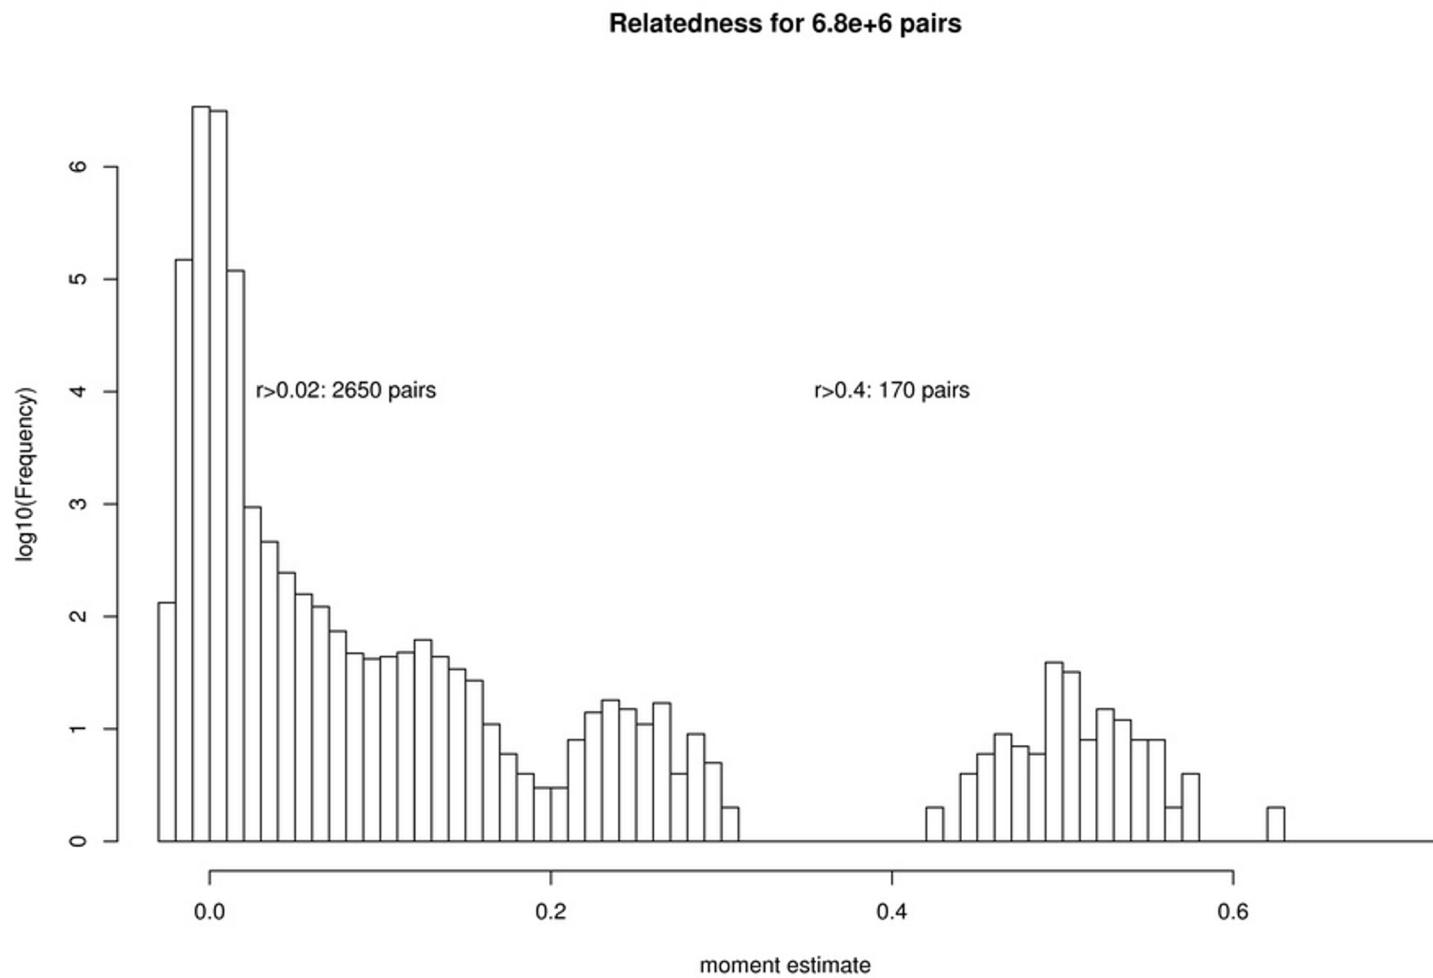

Empirical Distribution of Actual Additive Genetic Relationships  $r_{ij}$  of 4,401 Pairs of Full Sibs using up to 2,000 variants.

Values range: 0.374–0.617

The exact amount of IBD sharing varies considerably within a relative category (here full sibs).

Exception is the parent-offspring relationship that has IBDI throughout the genome.

# EXAMPLE RELATEDNESS FROM A COHORT

Correlation estimator was used as an estimate of  $r_{ij}$

We detect groups of  
50% (e.g. Full sibs)  
25% (e.g. Half sibs)  
12.5% (e.g. First cousins)

And almost all pairs are around 0%, "unrelated"

NOTE y-axis is on log-scale.

# KING APPLIED TO UK BIOBANK

$N \sim 500,000$   
 $1.2e+11$  pairs

From: The UK Biobank resource with deep phenotyping and genomic data

	Monozygotic twins	Parent-offspring	Full siblings	2 <sup>nd</sup> degree	3 <sup>rd</sup> degree	Total
Number of pairs	179	6,276	22,666	11,113	66,928	107,162

Counts are derived from the kinship coefficients (see [Methods](#)). The count of monozygotic twins is after excluding samples identified as duplicates ([Supplementary Information](#)).

# ARREST OF GOLDEN STATE KILLER

- “GSK” did tens of murders, assaults and rapes in 1970s and 1980s
- In 2018, police uploaded the DNA of the killer to GEDmatch
  - GEDmatch contains > million genome-wide data sets uploaded by volunteers in order to identify their own relatives
- The search returned a 3rd cousin of the killer (sharing a pair of great-great-grandparents)
  - With manual work, police traced down the suspect based on the info about the 3rd cousin
- Police took a DNA sample of the suspect – which matched to the killer
- In 2020, the suspect confessed and was sentenced for life

# FINDING RELATIVES FROM DATABASE

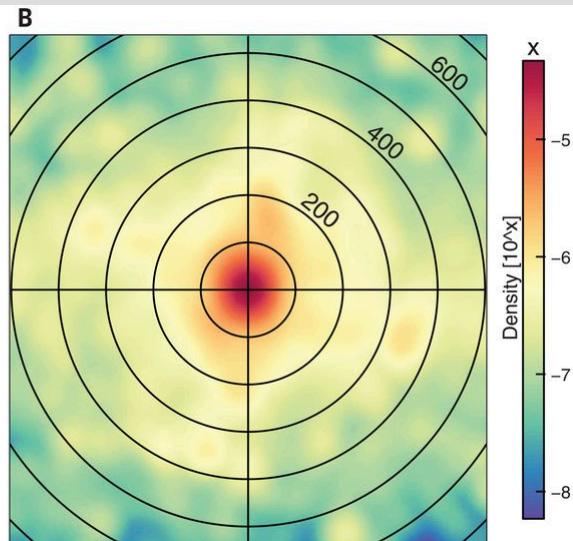

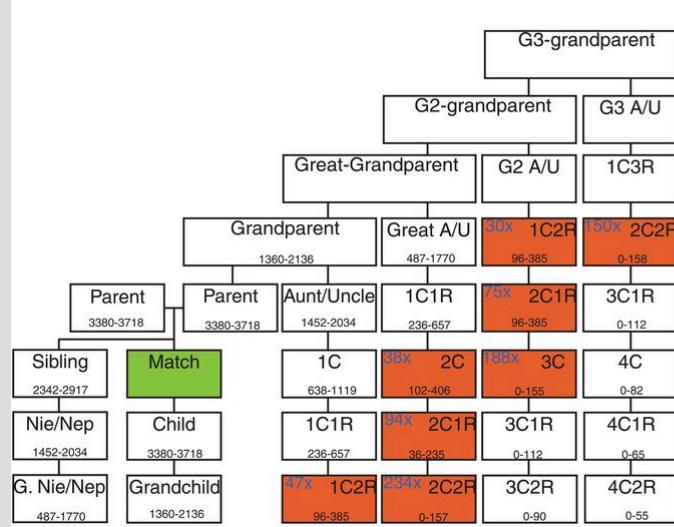

**A)** The probability of finding at least one relative for various IBD thresholds (top) with 1.28 million searches of DTC-tested individuals (red) and 30 random GEDmatch searches (gray). Light gray shading indicates the 95% CI for the GEDmatch estimates. The dashed line indicates the probability of a surname inference from Y chromosome data. The bottom panel shows the 95% CIs (circles) and average total IBD length (squares) for a first cousin once removed (1C1R) to a fourth cousin once removed (4C1R).

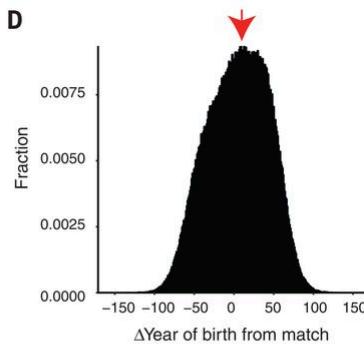

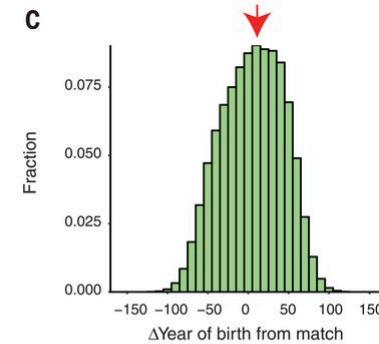

**(B)** A population-genetic theoretical model for the probability of finding relatives up to a certain type of cousinship as a function of the database coverage of the population. 1C to 4C indicate first to fourth cousins.

# FROM RELATIVE TO MATCH

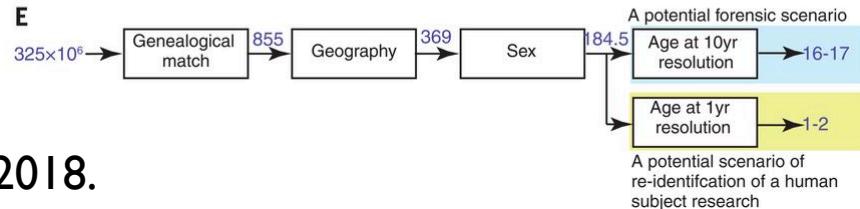

A

Density [100x]

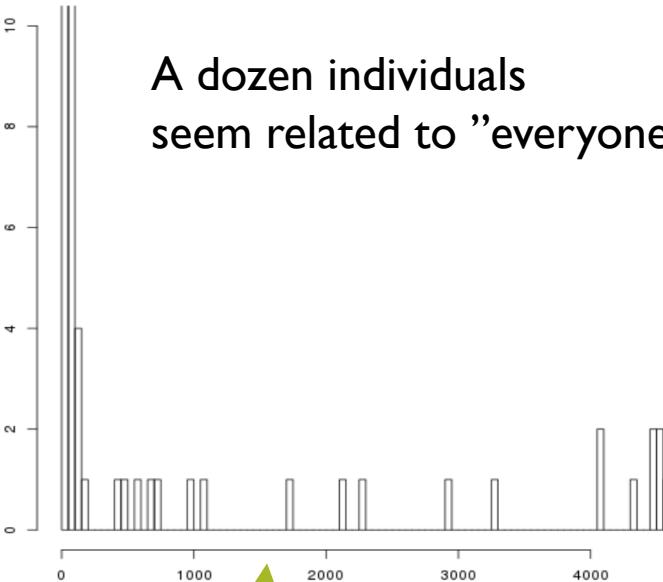

E

Tracing a person of interest from a distant match using demographic identifiers. (A) The possible relatives of a match (green) in a database. Each square represents a potential degree of relatedness. The range corresponds to the 5th to 95th percentile of shared IBD in centimorgans from (16). Red indicates relatives that could fit a bona fide 3C match (~100 cM). The average number of relatives is indicated in the top-left corner of each square on the basis of a fertility rate of 2.5 children per couple. Only genealogical relationships that are within 100-cM range include the average number of relatives. (B) An example of the geographical dispersion of 3C or 2C1R around the matched relative. Every circle indicates 100 km.

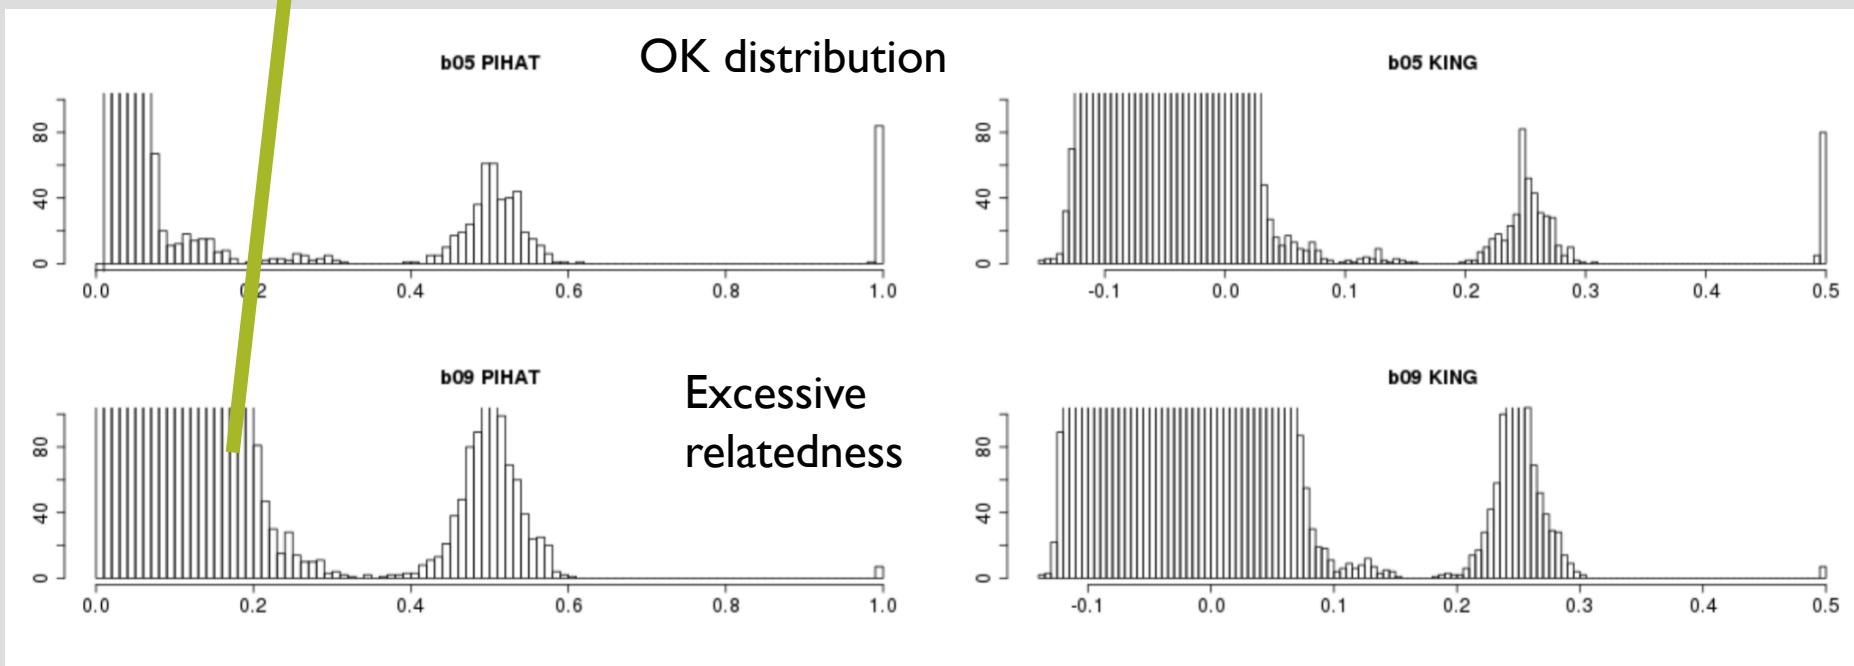

(C-D) The distribution of the expected age differences between matches and their potential relatives with a genetic distance of third cousins. The age distribution is shown at a 10-year resolution (C) and at a 1-year resolution (D). (E) The entire pipeline of using demographic identifiers along with a long-range familial match to identify a U.S. person (blue type indicates the average number of people after incorporating each piece of information.).

A dozen individuals seem related to "everyone"

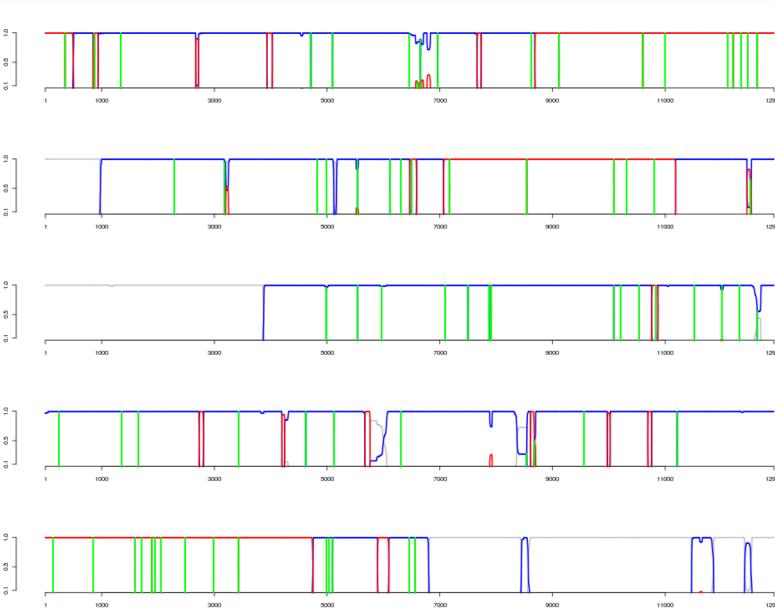

## RELATEDNESS AS QC TOOL

- High relatedness to many individuals can imply contamination
  - When DNA from many samples are mixed the result has excessive heterozygosity

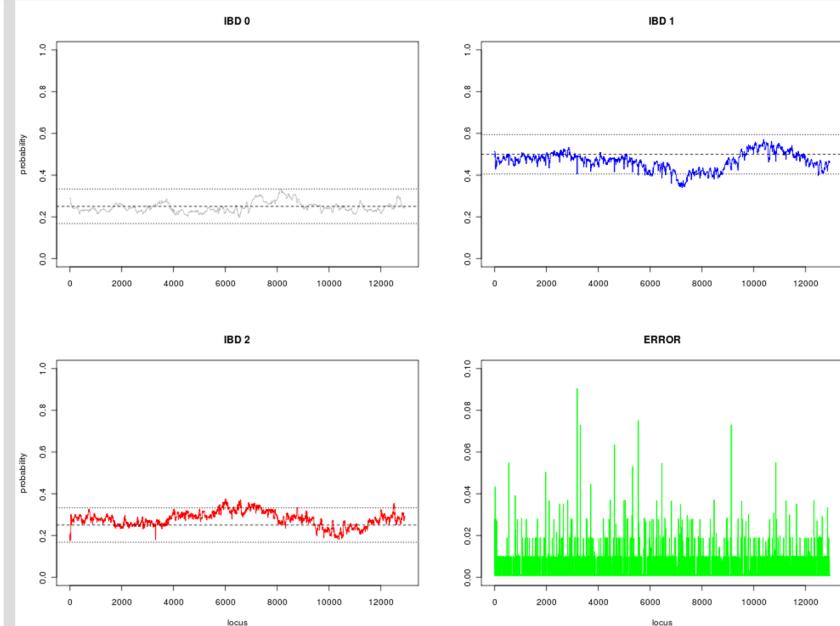

# USING IBD IN FULL SIBS TO IDENTIFY PROBLEMATIC SNPs

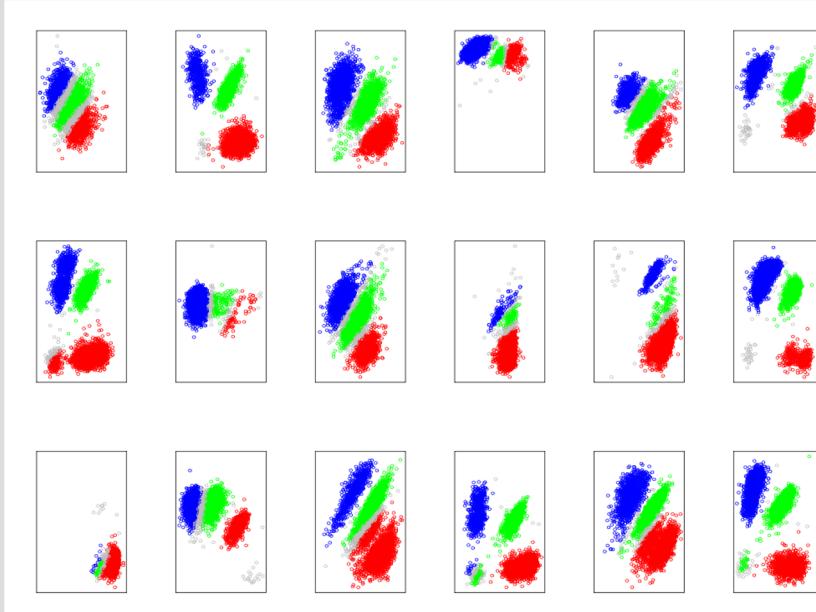

I. For each pair use a hidden Markov Model to model IBD state along the genome.  
Allows 4 states: IBD0, IBD1, IBD2 and ERROR.

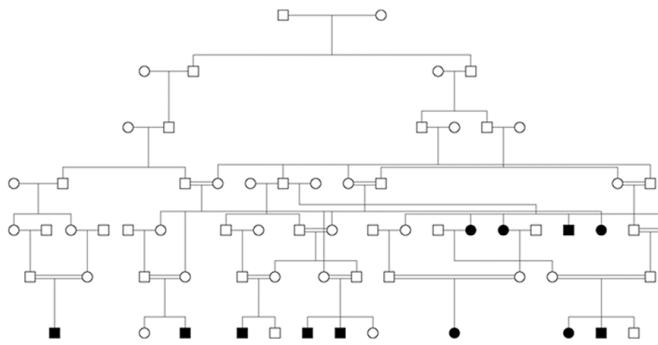

2. Check the average of each state along the genome.  
the ones with exceptionally many ERRORS are suspicious SNPs.

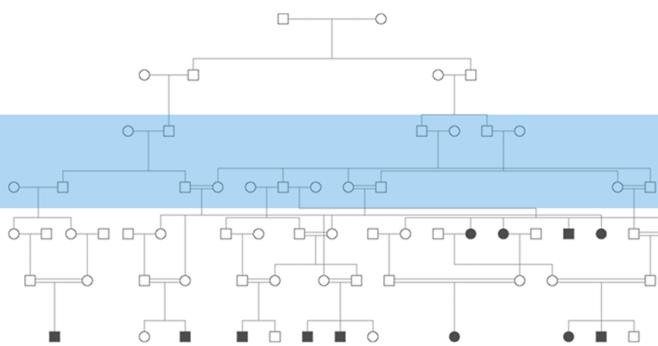

3. Manually check (some) of the suspicious SNPs to see whether there are obvious calling problems.  
(Yes there are!)

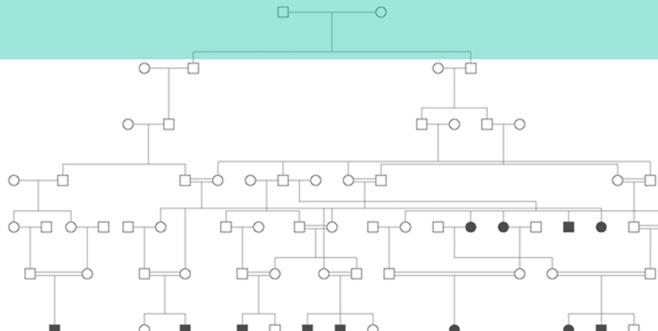

**A****B**

### CRYPTIC RELATEDNESS

**C**

### ANCESTRY

## POPULATION STRUCTURE

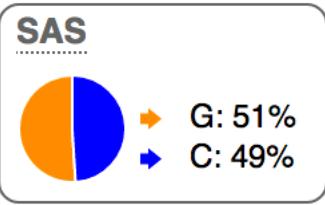

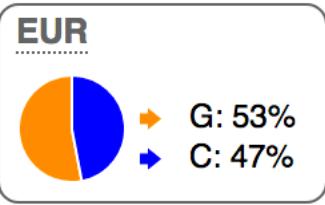

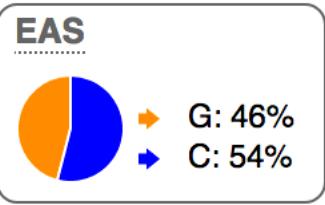

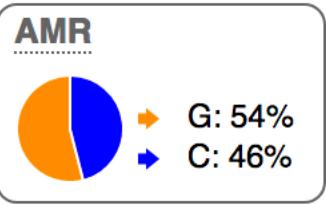

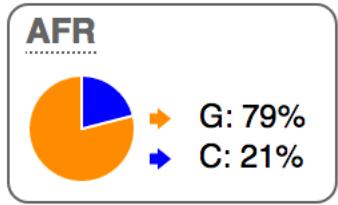

So far we have talked about close relatives that share Relatively long segment(s) of DNA.  
Now we move to more distant relatedness that we call "population structure".

Populations = "groups of individuals who **on average** are more closely related to the other members of the same group than to the members of another group"

Asian population vs European population  
Finnish population vs Swedish population  
Eastern Finns vs Western Finns

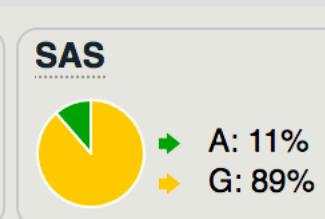

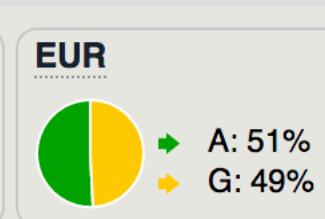

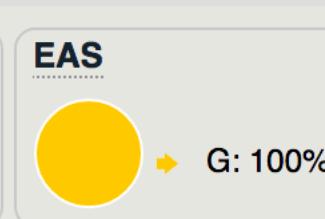

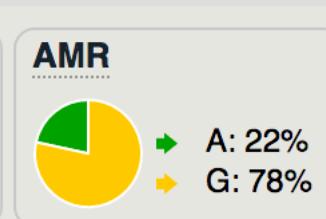

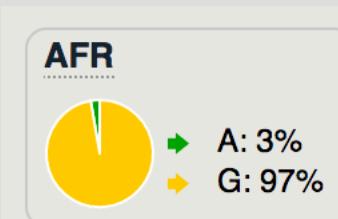

Population membership is not an objectively defined characteristic but depends on the level of detail.

# GLOBAL ALLELE FREQUENCY DIFFERENCES

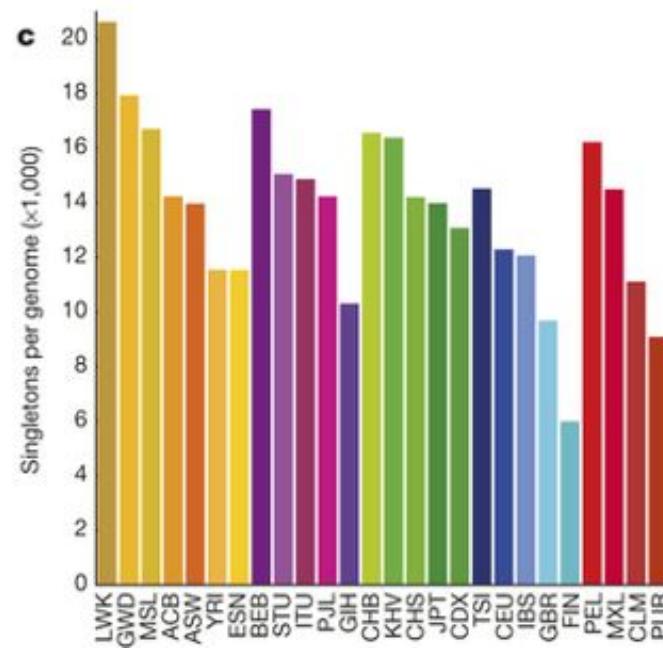

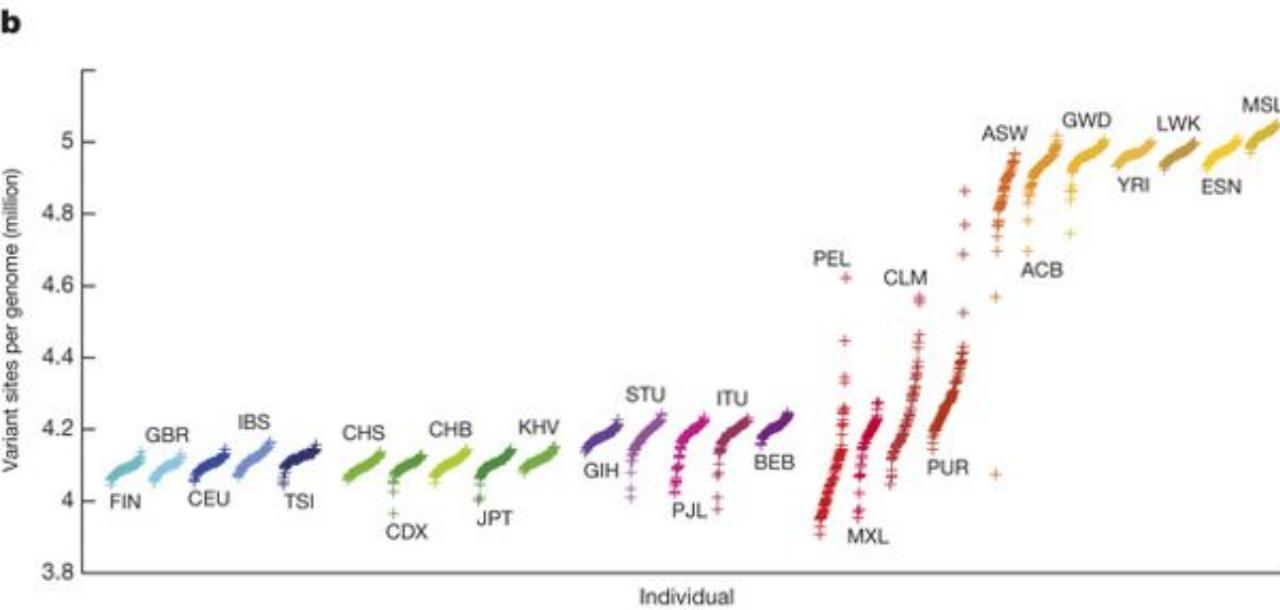

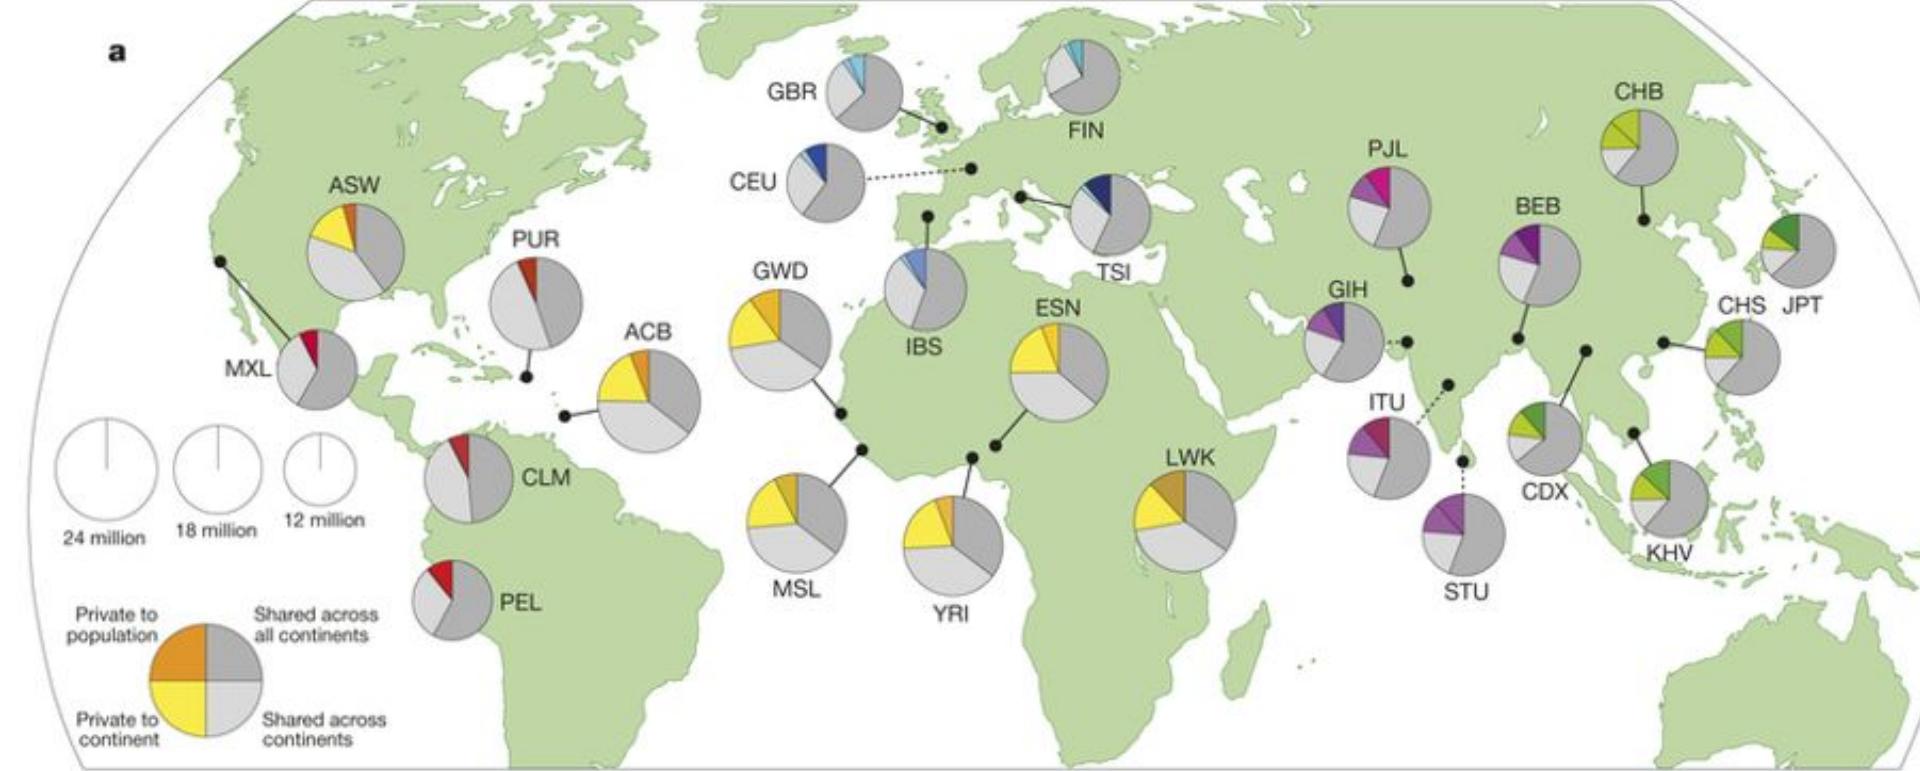

A "random" SNP

Frequencies can change due to genetic drift, selection, admixture or all of them.

rs4988235 (Lactase tolerance in Europeans, selection has had effect)

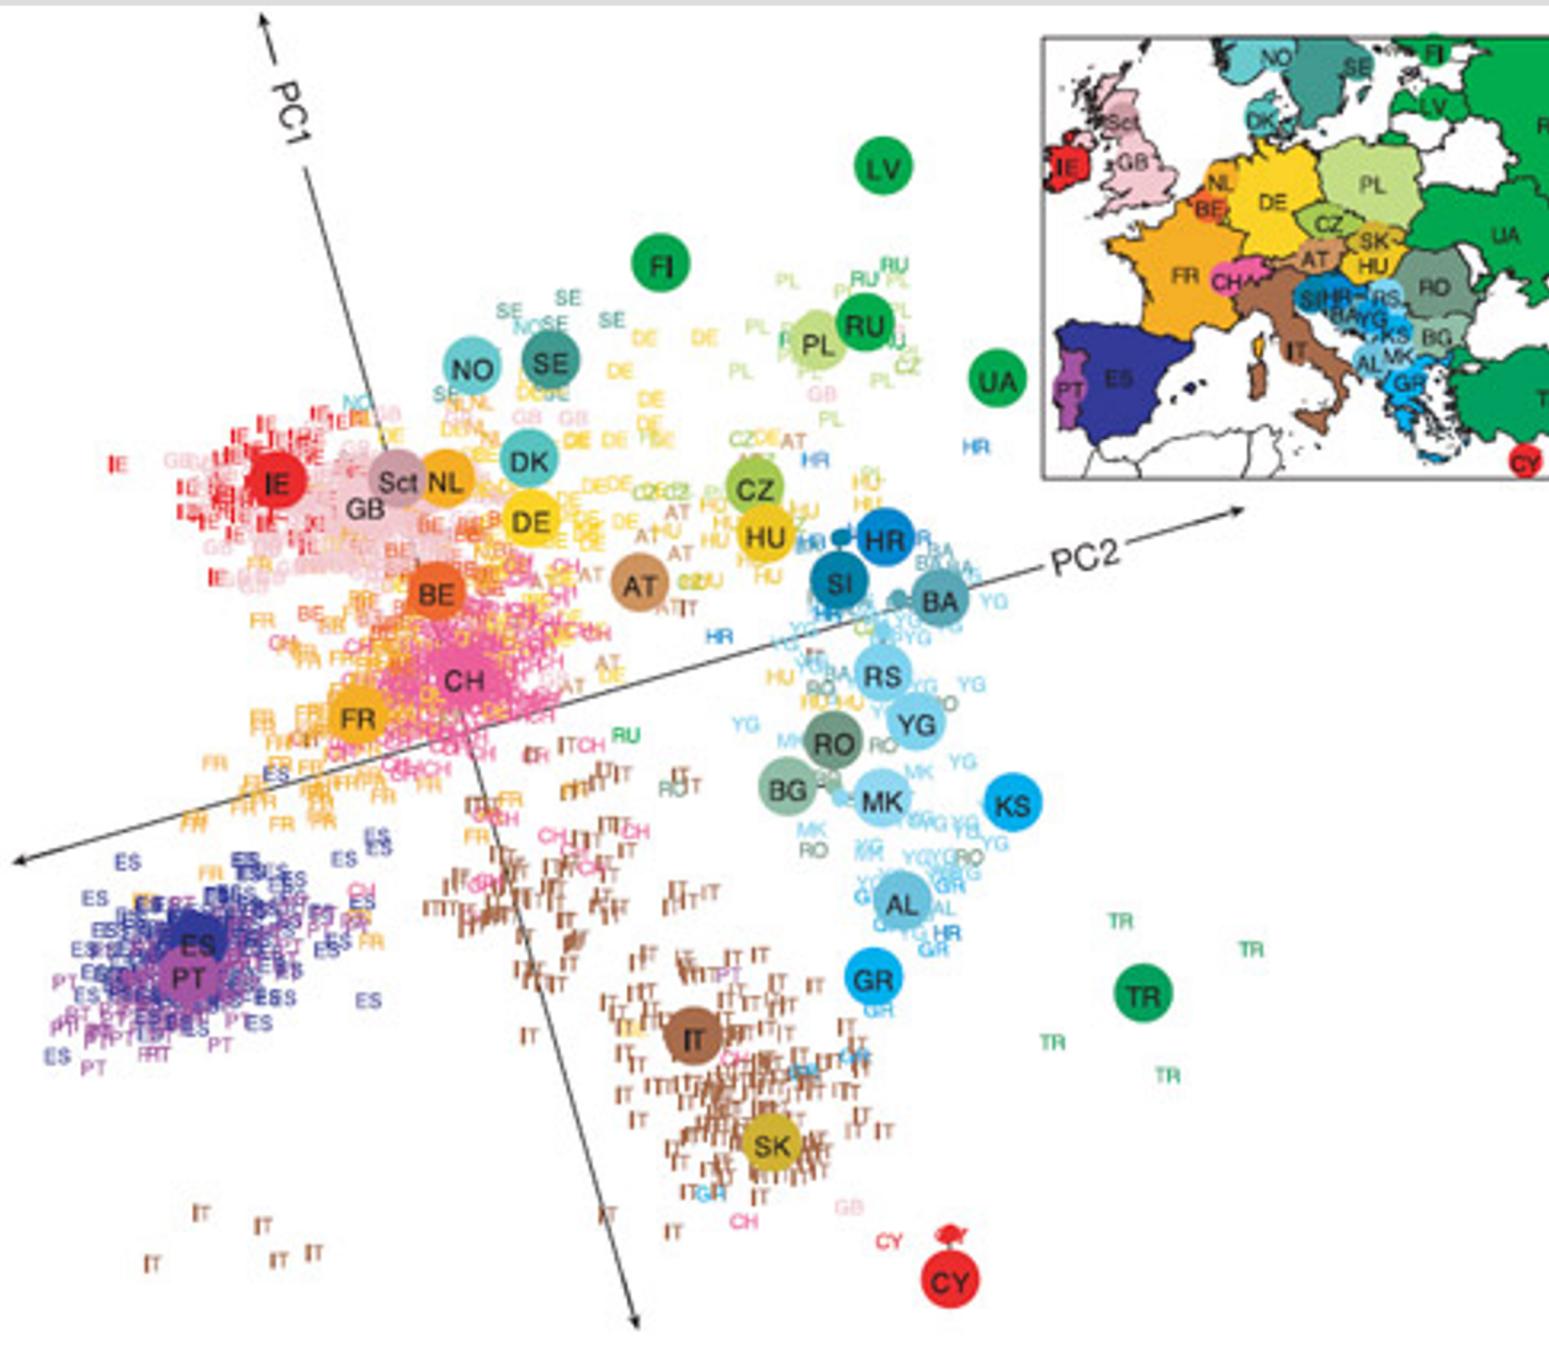

1000 Genomes project  
Nature 2015  
Figure 1.

**a,**  
Polymorphic variants.  
The area of each pie is proportional to the number of polymorphisms within a population. Pies are divided into four slices, according to Sharing pattern across globe.

**b,**  
The number of variant sites per genome.

**c,**  
The average number of singletons per genome.

# PCA OF EUROPEANS

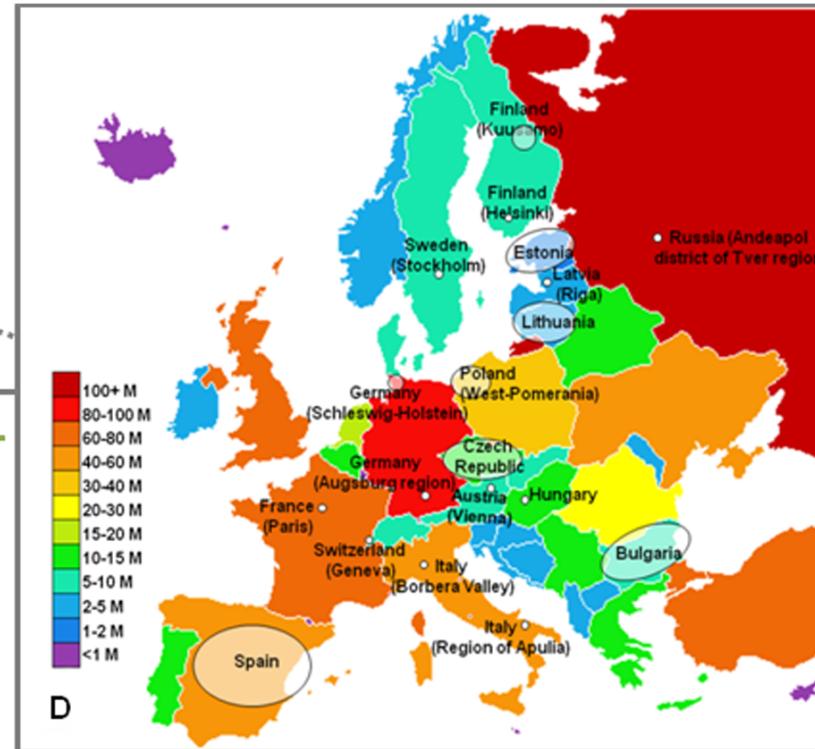

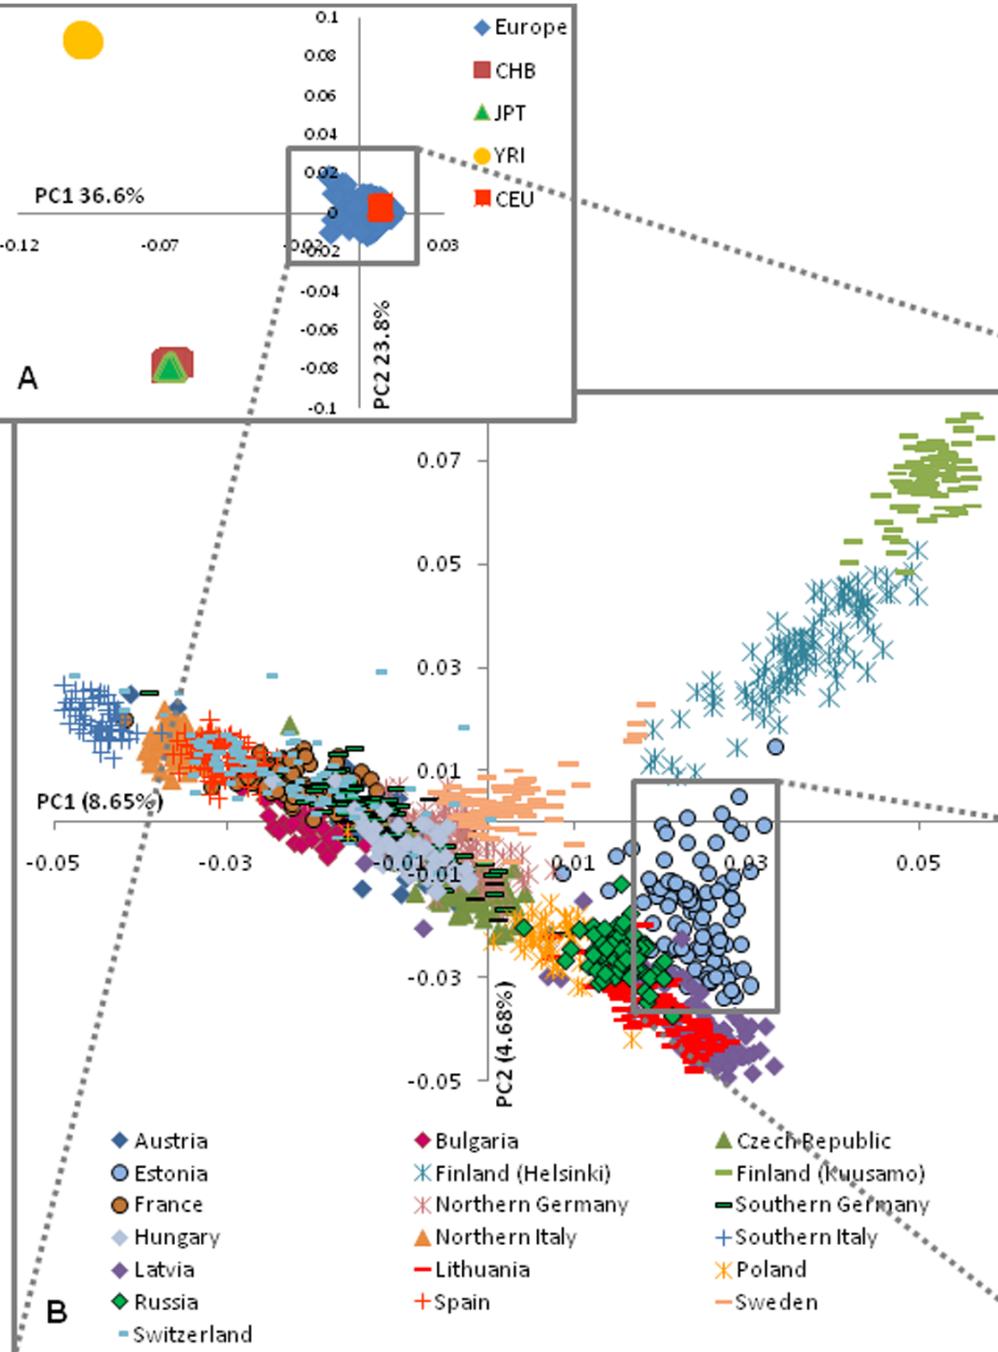

"Genes mirror geography  
within Europe"

Novembre et al. 2008, Nat Gen

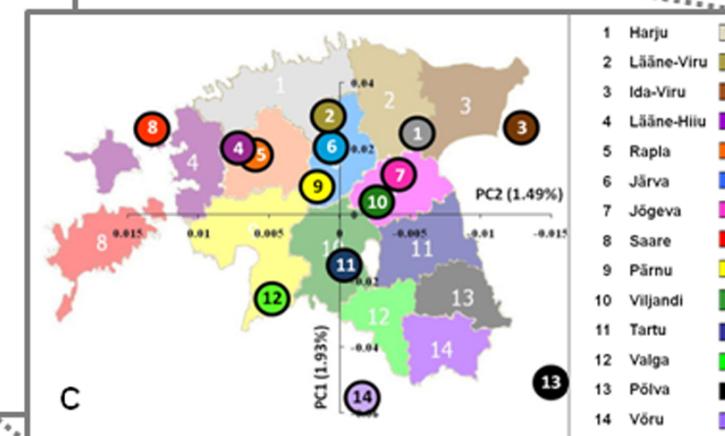

1400 individuals from Europe  
200,000 SNPs

In Fig., PC1 and PC2 rotated to  
match best the geographic map  
of Europe

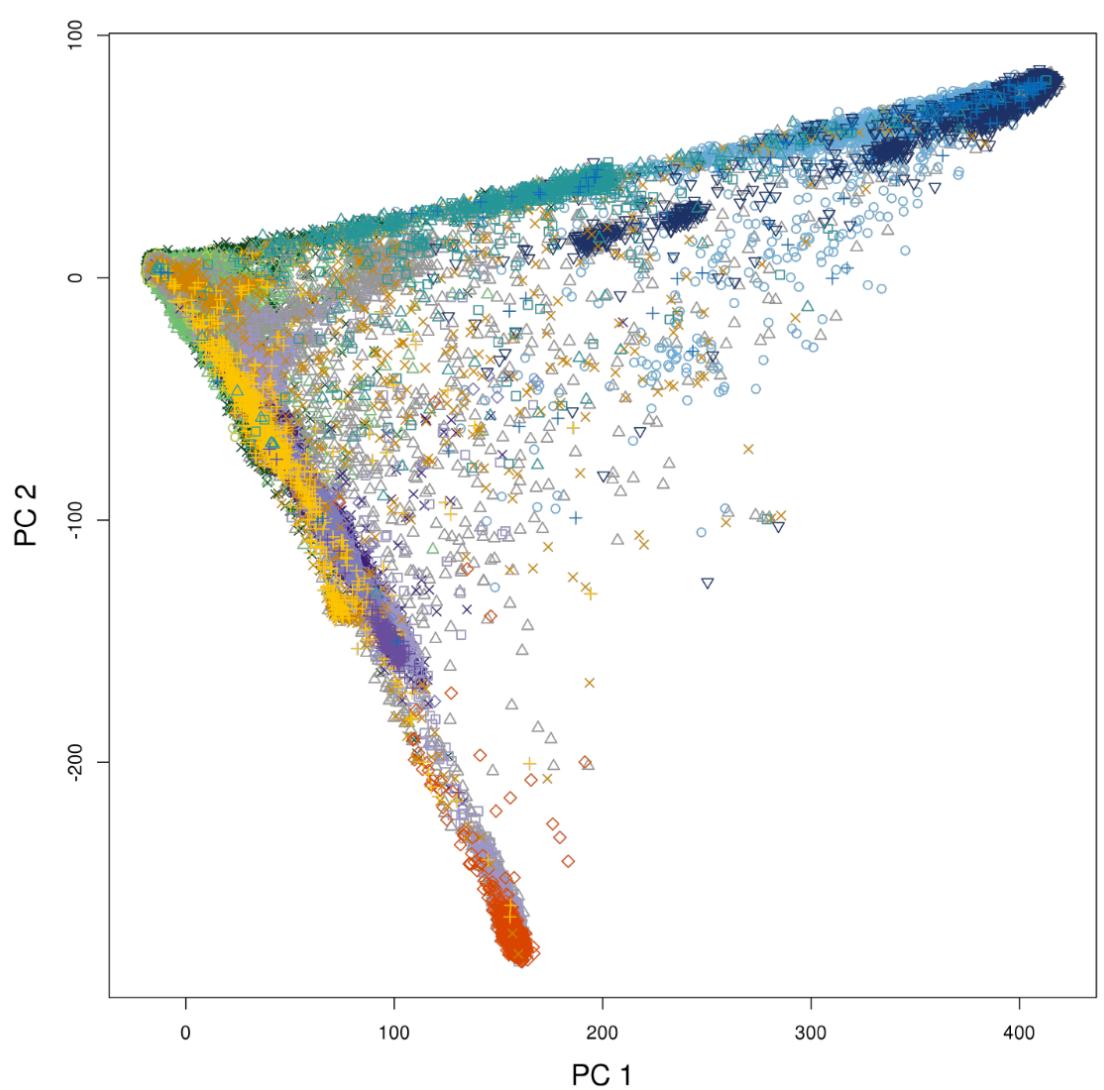

Three levels of structure as revealed by PC analysis:

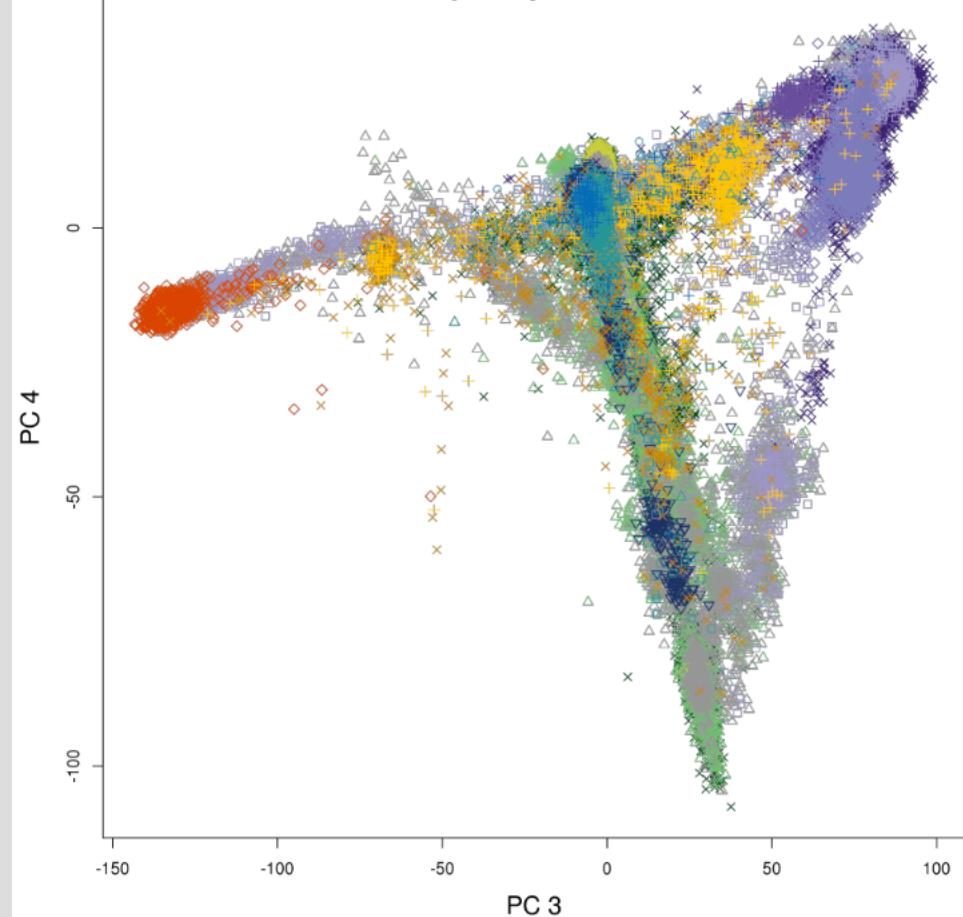

- inter-continental;
  - intra-continental; and
  - inside Estonia, where median values of the PC1&2 are shown.
- D) European map illustrating the origin of sample and population size.

CEU - Utah residents with ancestry from Northern and Western Europe,  
CHB – Han Chinese from Beijing,  
JPT - Japanese from Tokyo, and  
YRI - Yoruba from Ibadan, Nigeria.

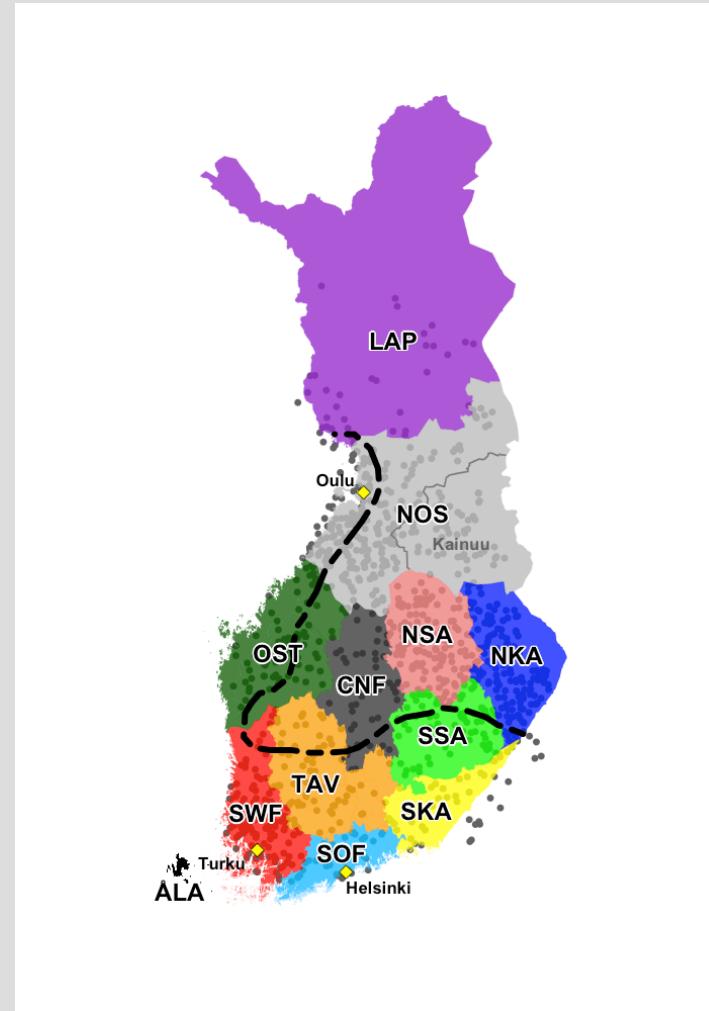

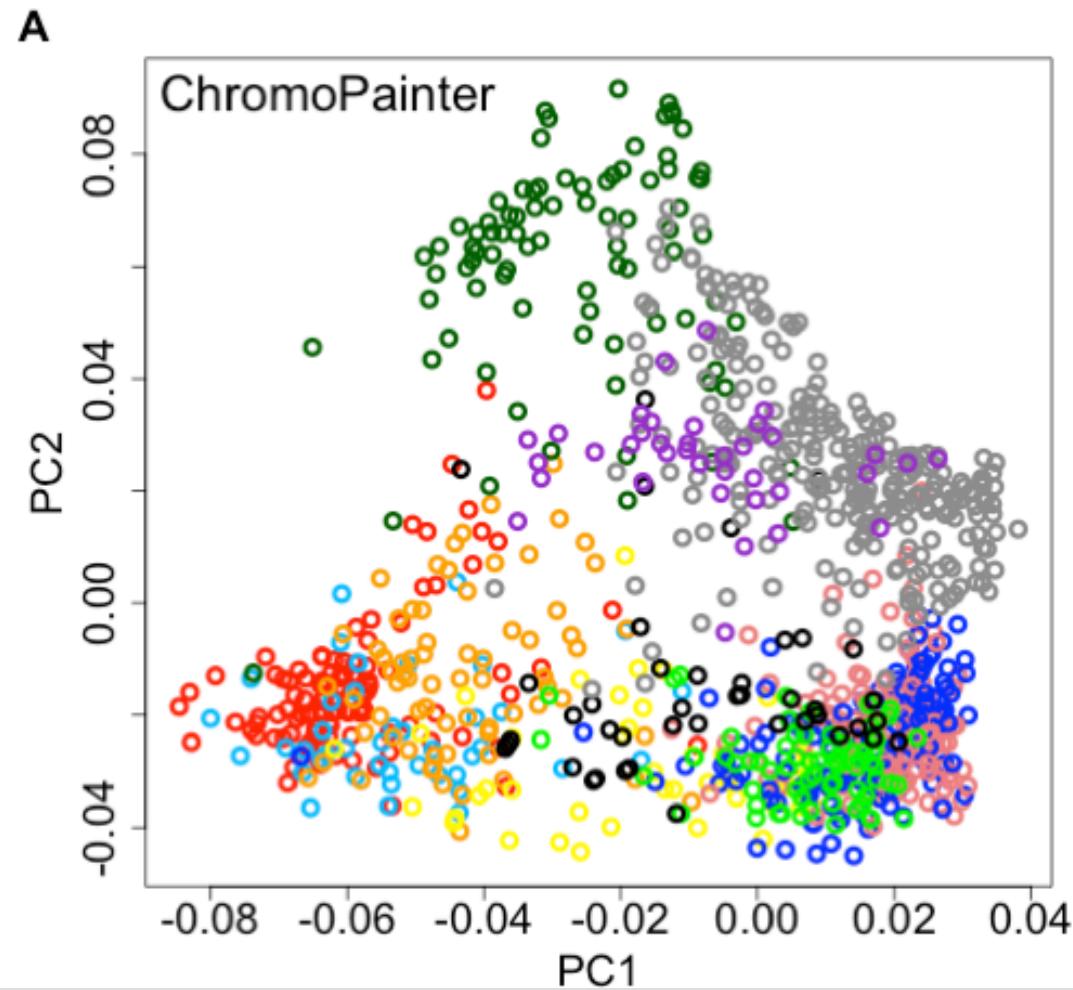

- UK Biobank genetic data with **n=407,000** and **p=150,000**,
- Done with FastPCA (Galinsky et al 2015) that implements *blanczos* algorithm, a stable version of power iteration

#### Self-reported ethnic background

×	British	▽	African
○	Irish	○	Caribbean
△	Any other white background	+	Any other Black background
×	Indian	+	White and Asian
◊	Pakistani	□	White and Black African
+	Bangladeshi	△	White and Black Caribbean
□	Any other Asian background	×	Any other mixed background
◇	Chinese	△	Other/Unknown

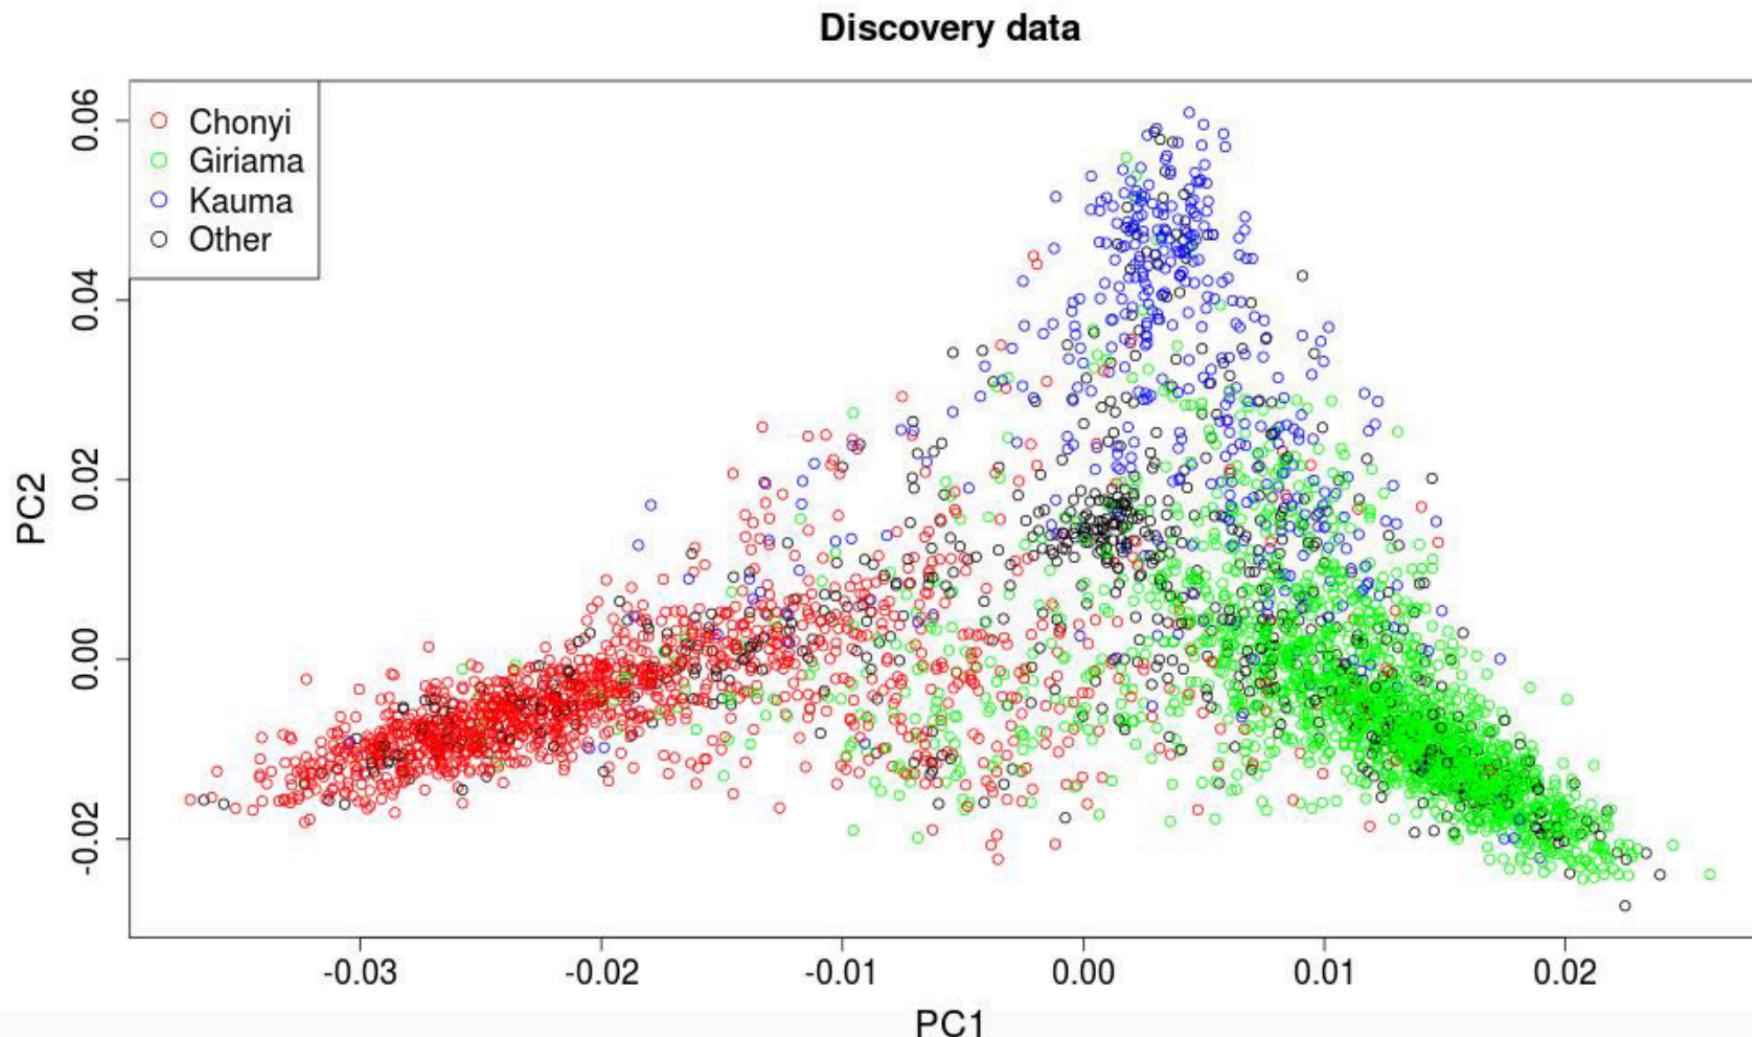

# PCA WITHIN FINLAND

Kerminen et al. 2017 G3. 1042 Finns with both parents born < 80km. PCA on left colored according to regions on right.

**Figure S5.** The first and second axes of the principal components analysis in the discovery dataset using 168,217 SNPs. Color coding represents A) reported ethnicity

A)

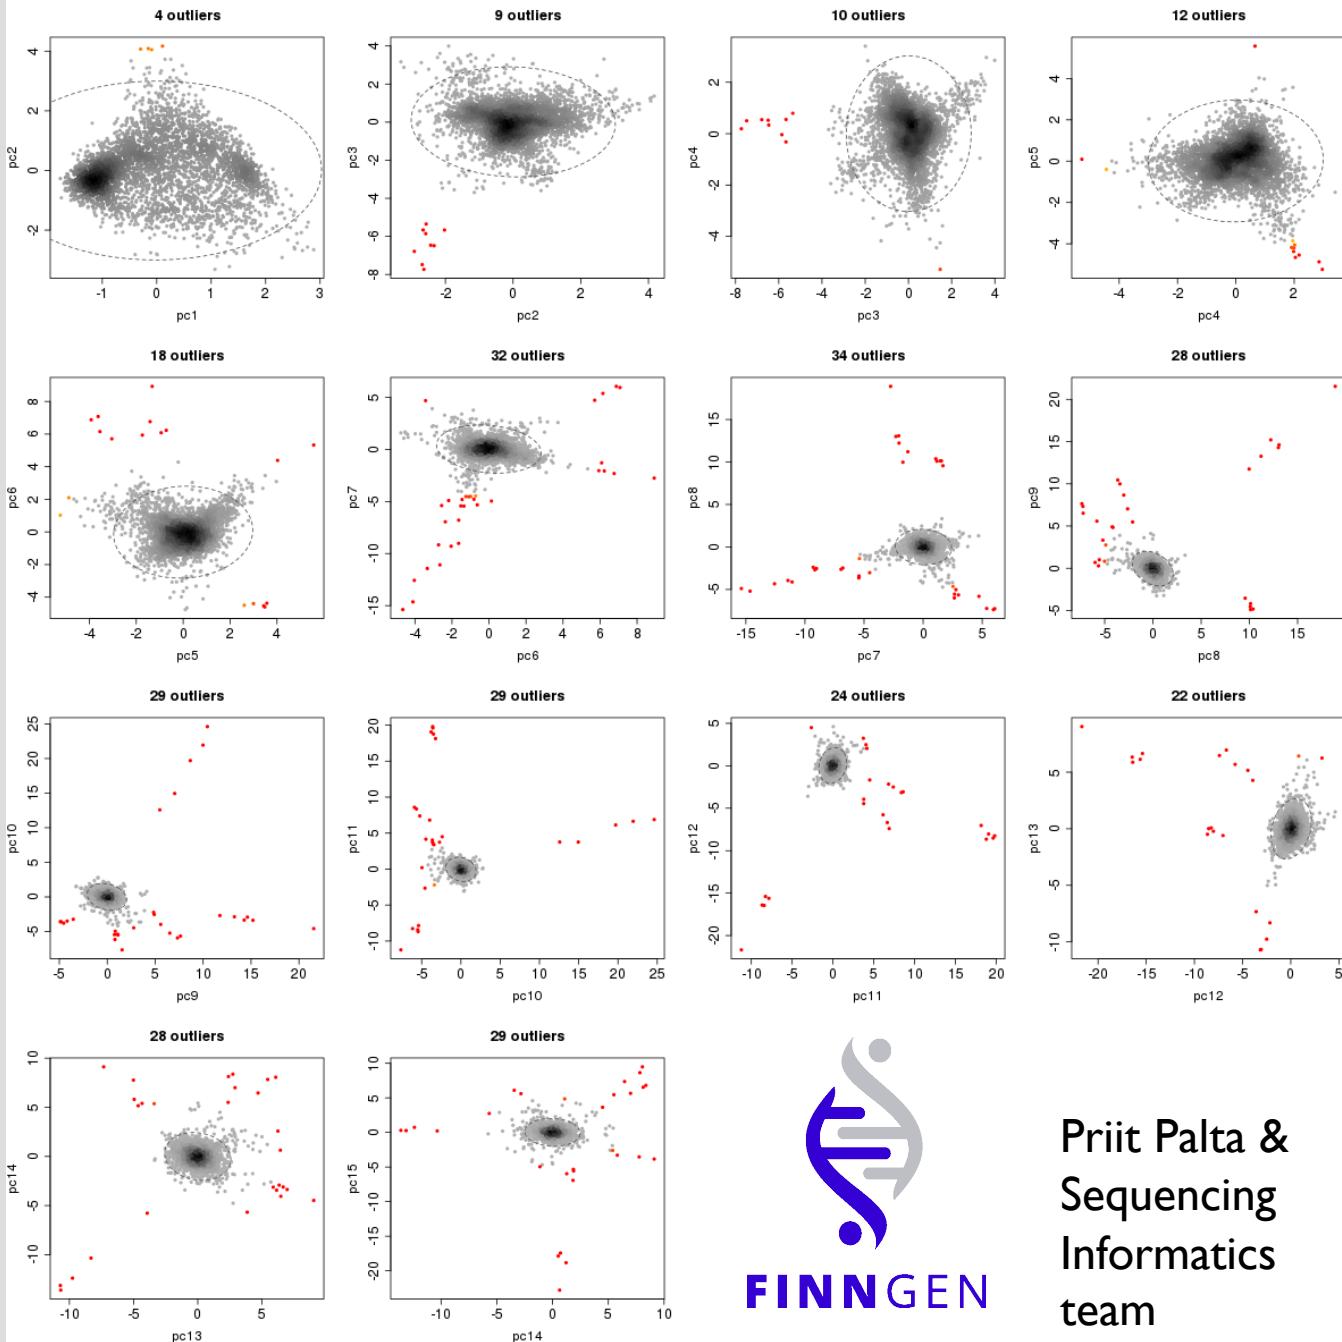

From a study of genetics of  
Bacteraemia in  
Kenyan Children

First 2 PCs associate with  
ethnic group.

(Rautanen et al. 2016 AJHG)

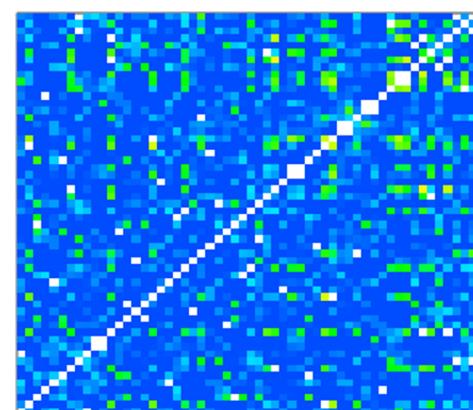

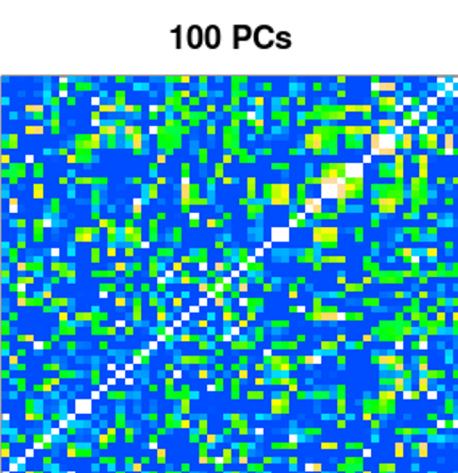

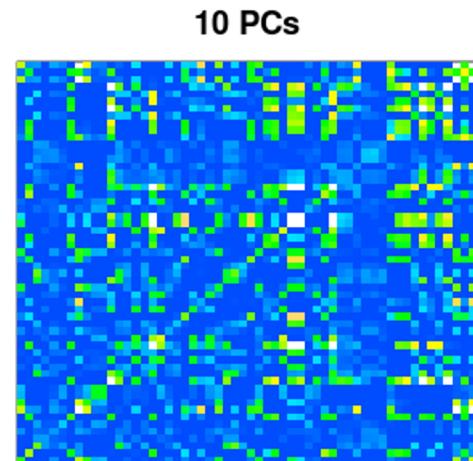

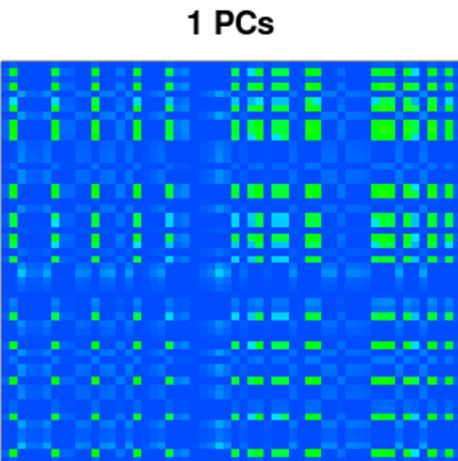

# PCA AS QUALITY CONTROL METHOD

- PCA can be used to inform if data have samples with
  - relative groups
  - different ancestry
  - technical problems (e.g. contamination)
- These are typically removed from further analyses

Sequencing  
Informatics  
team

# GRM IS BUILT FROM PCS

$$R = UDU^T = \sum_{i=1}^n d_i U_{\cdot i} U_{\cdot i}^T$$

R is genetic relatedness matrix (GRM)

U has eigenvectors of R as columns

D has eigenvalues on diagonal

$U_{\cdot i}$  is the  $i^{\text{th}}$  column, i.e., scores of individuals on PC  $i$

$U_{\cdot i} U_{\cdot i}^T$  is a rank-1 matrix

Any subset of PCs corresponds to a truncated GRM
